Introduction

● Typical machine learning approaches deals with fixed input or variable-length input and fixed output
  ○ Image Classification
  ○ Sentiment Analysis
  ○ ...

● Certain tasks require the machine learning approach to generate variable-length outputs
  ○ Summary Generation
  ○ Machine Translation
  ○ Image Descriptions

● We will look at Deep Learning Approaches for such tasks, specifically we focus on Machine Translation
What is Machine Translation?

Automatic conversion of text/speech from one natural language to another

Be the change you want to see in the world

वह परिवर्तन बनो जो संसार में देखना चाहते हो
Outline

● Introduction
● Neural Machine Translation
● Summary
Neural Machine Translation
SMT, Rule-based MT and Example based MT manipulate symbolic representations of knowledge

Every word has an atomic representation, which can’t be further analyzed.

No notion of similarity or relationship between words
- Even if we know the translation of home, we can’t translate house if it an OOV

Difficult to represent new concepts
- We cannot say nothing about ‘mansion’ if it comes up at test time
- Creates problems language model as well ⇒ whole are of smoothing exists to overcome this problem
Neural Network techniques work with distributed representations

- No element of the vector represents a particular word
- The word can be understood with all vector elements
- Hence distributed representation
- But less interpretable

Every word is represented by a vector of numbers

<table>
<thead>
<tr>
<th></th>
<th>home</th>
<th>water</th>
<th>house</th>
<th>tap</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.5</td>
<td>0.2</td>
<td>0.55</td>
<td>0.24</td>
</tr>
<tr>
<td></td>
<td>0.6</td>
<td>0.9</td>
<td>0.58</td>
<td>0.6</td>
</tr>
<tr>
<td></td>
<td>0.7</td>
<td>0.3</td>
<td>0.77</td>
<td>0.4</td>
</tr>
</tbody>
</table>

Can define similarity between words
- Vector similarity measures like cosine similarity
- Since representations of home and house, we may be able to translate house

New concepts can be represented using a vector with different values

Symbolic representations are continuous representations
- Generally computationally more efficient to work with continuous values
- Especially optimization problems
**Encode - Decode Paradigm**

**Entire input sequence is processed before generation starts**
⇒ In PBSMT, generation was piecewise

**The input is a sequence of words, processed one at a time**

- While processing a word, the network needs to know what it has seen so far in the sequence
- Meaning, know the history of the sequence processing
- Needs a special kind of neural: **Recurrent neural network unit** which can keep state information
Encode - Decode Paradigm Explained

Use two RNN networks: the encoder and the decoder

(1) Encoder processes one sequence at a time

(2) A representation of the sentence is generated

(3) This is used to initialize the decoder state

(4) Decoder generates one element at a time

(5)… continue till end of sequence tag is generated

Encoding

Decoding
This approach reduces the entire sentence representation to a single vector

Two problems with this design choice:

- A single vector is not sufficient to represent to capture all the syntactic and semantic complexities of a sentence
  - Solution: Use a richer representation for the sentences

- Problem of capturing long term dependencies: The decoder RNN will not be able to make use of source sentence representation after a few time steps
  - Solution: Make source sentence information when making the next prediction
  - Even better, make RELEVANT source sentence information available

These solutions motivate the next paradigm
Represent the source sentence by the set of output vectors from the encoder.

Each output vector at time $t$ is a contextual representation of the input at time $t$.

*Note: in the encoder-decode paradigm, we ignore the encoder outputs.*

Let’s call these encoder output vectors *annotation vectors*.
How should the decoder use the set of annotation vectors while predicting the next character?

Key Insight:
(1) Not all annotation vectors are equally important for prediction of the next element
(2) The annotation vector to use next depends on what has been generated so far by the decoder

eg. To generate the 3\textsuperscript{rd} target word, the 3\textsuperscript{rd} annotation vector (hence 3\textsuperscript{rd} source word) is most important

One way to achieve this:
Take a weighted average of the annotation vectors, with more weight to annotation vectors which need more focus or attention

This averaged context vector is an input to the decoder
Let's see an example of how the attention mechanism works during decoding

For generation of $i^{th}$ output character:

- $c_i$: context vector
- $a_{ij}$: annotation weight for the $j^{th}$ annotation vector
- $o_j$: $j^{th}$ annotation vector

$$c_i = \sum_{j=1}^{n} a_{ij} o_j$$
में → ने → किताब → पढ़ी → <EOS>

$h_0 \rightarrow h_1 \rightarrow h_2 \rightarrow h_3 \rightarrow h_4 \rightarrow h_5$

$c_5$

$a_{51} \rightarrow o_1$

$a_{52} \rightarrow o_2$

$a_{53} \rightarrow o_3$

$a_{54} \rightarrow o_4$
But we do not know the attention weights? How do we find them?

Let the training data help you decide!!

Idea: Pick the attention weights that maximize the translation accuracy (more precisely, decrease training data loss)

- Note ⇒ no separate language model
- Neural MT generates fluent sentences
- Quality of word order is better
- No combinatorial search required for evaluating different word orders:
  - Decoding is very efficient compared to PBSMT
- Exciting times ahead!
Read the entire sequence and predict the output sequence (using function $F$)

- Length of output sequence need not be the same as input sequence
- Prediction at any time step $t$ has access to the entire input
- A very general framework
Sequence to Sequence transformation is a very general framework

Many other problems can be expressed as sequence to sequence transformation

- **Summarization**: Article ⇒ Summary
- **Question answering**: Question ⇒ Answer
- **Image labelling**: Image ⇒ Label
- **Transliteration**: character sequence ⇒ character sequence
